

Amendments to the Claims:

This listing of claims will replace all prior versions, and listings, of claims in the application:

Listing of Claims:

Claim 1. (Previously Canceled)

Claim 2. (Previously Canceled)

Claim 3. (Previously Canceled)

Claim 4. (Previously Canceled)

Claim 5. (Previously Canceled)

Claim 6. (Previously Amended)

An internal combustion engine, comprising;

- (a) at least one combustion cylinder including a cylinder and a reciprocating piston, said reciprocating piston oscillating within said cylinder in cycles which include a power stroke in which said piston moves from a top dead center position to a bottom dead center position and a return stroke in which said piston moves from said bottom dead center position to said top dead center position, said power stroke further divided into a first half portion and a second half portion and said return stroke further divided into a first half portion and a second half portion,
- (b) a compressor for producing compressed air,

- (c) a compressed air conduit communicating between said compressor and said combustion cylinder, said compressed air conduit including a reservoir for accumulating and storing said compressed air, (ii) a heat rejecting portion for cooling said compressed air, (iii) an outlet portion for conveying pressurized air to said combustion cylinder, (iv) a hot conduit for conveying uncooled compressed air to said outlet portion and (v) a cool conduit for conveying cooled pressurized air from said heat rejection portion to said outlet portion and at least one valve communicating between one of said hot conduit and said cool conduit for adjusting the proportion of cooled compressed air and uncooled compressed air for adjusting the temperature of the pressurized air in said outlet portion,
- (d) an injection valve for opening and closing communication between said outlet portion of said compressed air conduit and said at least one combustion cylinder thereby intermittently allowing passage of a volume of compressed air into said combustion cylinder,
- (e) a fuel injector for injecting fuel into said volume of compressed air,
- (f) an exhaust means for releasing exhaust from said combustion cylinder,
- (g) a timing system for:
 - (i) opening said injection valve when said piston of said at least one combustion cylinder is generally in said second half portion of said return stroke to transfer said volume of compressed air into said combustion cylinder,

(ii) activating said fuel injector after said compressed air valve has opened to inject fuel into said volume of compressed air to produce a combustible fuel - air mixture for subsequent combustion and expansion during said power stroke, and,

(iii) opening said exhaust means after said piston has entered said second portion of said power stroke to allow escape of exhaust gases.

Claim 7. (Previously Canceled)

Claim 8. (Previously Canceled)

Claim 9. (Previously Amended) The internal combustion engine of claim 6, wherein,

said injection valve is a rotary valve that is operatively associated with said piston of said at least one combustion cylinder by said timing system, said rotary valve including a passage for establishing intermittent communication between said compressed air conduit and said at least one combustion cylinder during a portion of said cylinder cycle within said second half portion of said return stroke.

Claim 10. (Previously Amended) The internal combustion engine of claim 6, wherein,

said at least one combustion cylinder further includes a connecting rod connecting said piston with a crankshaft for rotation in response to said oscillating movement of said piston, and wherein,

said injection valve is an indexed rotary valve, said rotary valve including a valve body and an indexing means operatively coupling said valve body with said crankshaft for causing intermittent rotation of said valve body in response to said continuous rotation of said crankshaft substantially when said piston is in said second half portion of said return stroke, said valve body including a passage for providing communication between said compressed air conduit and said at least one combustion cylinder during a portion of said intermittent rotation of said valve body.

Claim 11. (Previously Amended) The internal combustion engine of claim 6, wherein,

said at least one combustion cylinder further includes a connecting rod connecting said piston with a crankshaft for rotation in response to said oscillating movement of said piston, and wherein,

said injection valve is an indexed rotary valve disposed between said compressed air conduit and said combustion cylinder, said indexed rotary valve further comprising a valve housing for enclosing a valve housing volume in pneumatic communication with said compressed air conduit, said valve housing having an injection port for communicating said valve housing volume with said combustion cylinder, a valve body rotatably disposed within said valve housing in sealed relationship with said injection port and including at least one passage for intermittently establishing pneumatic communication between said valve housing volume and said injection port, and an indexing means operatively associating said valve body and said crankshaft for

intermittently rotating said valve body such that said at least one passage of said valve body establishes pneumatic communication between said valve housing volume and said injection port to allow passage of said volume of compressed air into said combustion cylinder.

Claim 12. (Previously Amended) The internal combustion engine of claim 6, wherein,

said at least one combustion cylinder further includes a connecting rod connecting said piston with a crankshaft for rotation in response to said oscillating movement of said piston, and,

said injection valve is an indexed rotary valve disposed between said compressed air conduit and said combustion cylinder, said indexed rotary valve further comprising a valve housing for enclosing a valve housing volume in pneumatic communication with said compressed air conduit, said valve housing having an injection port communicating said valve housing volume with said combustion cylinder, a valve body rotatably disposed within said valve housing in sealed relationship with said injection port and including at least one passage for intermittently opening pneumatic communication between said valve housing volume and said injection port, and an indexing mechanism coupling between said valve body and said crankshaft for intermittently rotating said valve body such that said at least one passage of said valve body opens pneumatic communication between said valve housing and said injection port to convey said injection air into said combustion cylinder, said indexing mechanism including a drive wheel and an indexing wheel, said drive wheel coupled to said crankshaft for continuous

rotation therewith, said drive wheel having at least one cog and a retaining disc, said indexing wheel coupled to said valve body and having at least one slot for receiving said at least one cog of said drive wheel for intermittent motion of said indexing wheel in response to continuous rotating motion of said cog of said drive wheel during a first portion of the rotational cycle of said drive wheel, said indexing wheel further comprising at least one retaining feature compatible with said retaining disc of said drive wheel for retaining said indexing wheel in a stationary position during a second portion of the rotational cycle of said drive wheel, said valve body and said indexing wheel coupled such that pneumatic communication between said at least one passage of said valve body and said injection port occurs during said first portion of the rotational cycle of said drive wheel, said drive wheel and said crankshaft also coupled such that said first portion of the rotational cycle of said drive wheel occurs substantially when said piston is in said second half portion of said return stroke.

Claim 13. (Previously Canceled)

Claim 14. (Previously Amended) The internal combustion engine of claim 6, wherein,
said compressor includes a compression cylinder.

Claim 15. (Previously Amended) The internal combustion engine of claim 6, wherein,
said at least one combustion cylinder includes a crankshaft and a connecting rod coupling the piston and the crankshaft, and

said compressor includes at least one compression cylinder including a piston mechanically coupled to said crankshaft.

Claim 16.(Previously Amended) An internal combustion engine, comprising;

(a) at least one combustion cylinder including a cylinder and a reciprocating piston, said reciprocating piston oscillating within said cylinder in cycles which include a power stroke in which said piston moves from a top dead center position to a bottom dead center position and a return stroke in which said piston moves from said bottom dead center position to said top dead center position, said power stroke further divided into a first half portion and a second half portion and said return stroke further divided into a first half portion and a second half portion, said at least one combustion cylinder further including a crankshaft mechanically coupled to said piston,

(b) a compressor for producing compressed air mechanically coupled to a compressor shaft, said crankshaft of said at least one combustion cylinder and said compressor shaft operatively associated such that the ratio of their speeds of rotation is adjustable for adjustment of the effective compression ratio of said engine,

(c) a compressed air conduit communicating between said compressor and said combustion cylinder,

(d) an injection valve for opening and closing communication between said compressed air conduit and said at least one combustion cylinder thereby intermittently allowing passage of a volume of compressed air into said combustion cylinder,

- (e) a fuel injector for injecting fuel into said volume of compressed air,
- (f) an exhaust means for releasing exhaust from said combustion cylinder,
- (g) a timing system for
 - (i) opening said injection valve when said piston of said at least one combustion cylinder is generally in said second half portion of said return stroke to transfer said volume of compressed air into said combustion cylinder,
 - (ii) activating said fuel injector after said compressed air valve has opened to inject fuel into said volume of compressed air to produce a combustible fuel - air mixture for subsequent combustion and expansion during said power stroke, and,
 - (iii) opening said exhaust means after said piston has entered said second portion of said power stroke to allow escape of exhaust gases.

Claim 17. (Previously Amended) The internal combustion engine of claim 16, wherein, said crankshaft and said compressor shaft are operatively connected by a variable ratio gear box adapted for operation between a first ratio in which the ratio of speeds of rotation of said compressor shaft to said crankshaft is relatively low and a second ratio in which the ratio of speeds of rotation of said compressor shaft to said crankshaft is relatively high, said first ratio for maintaining air pressure in said compressed air conduit at a relatively low pressure corresponding to a relatively low volumetric compression ratio, said second ratio for maintaining air pressure in said compressed air conduit at a relatively high pressure corresponding to a relatively high compression ratio, said first

ratio for relatively high efficiency and relatively low power density operation, said second ratio for relatively lower efficiency and relatively high power density operation.

Claim 18. (Previously Amended) The internal combustion engine of claim 16, wherein,
said compressed air conduit further comprises a heat rejecting portion for cooling
said at least a portion of said compressed air.

Claim 19. (Previously Amended) The internal combustion engine of claim 16, wherein,
said compressed air conduit further comprises (i) a reservoir for accumulating and
storing said compressed air and (ii) a heat rejecting portion for cooling said compressed
air.

Claim 20. (Previously Amended) The internal combustion engine of claim 16, wherein,
said compressed air conduit further comprises (i) a reservoir for accumulating and
storing said compressed air, (ii) a heat rejecting portion for cooling said compressed air,
(iii) an outlet portion for conveying pressurized air to said combustion cylinder, (iv) a hot
conduit for conveying uncooled compressed air to said outlet portion and (v) a cool
conduit for conveying cooled pressurized air from the heat rejection portion to said outlet
portion and at least one valve communicating between one of said hot conduit and said
cool conduit for adjusting the proportion of cooled compressed air and uncooled
compressed air for adjusting the temperature of the pressurized air in said outlet portion.

Claim 21. (Previously Canceled)

Claim 22. (Previously Canceled)

Claim 23. (Previously Amended) In combination with an internal combustion engine of the type including at least one combustion chamber which oscillates between a minimum volume and a maximum volume during alternating expansion portions and contraction portions of successive cycles for causing powered rotation of a crank shaft, a system for injecting compressed air into said combustion chamber comprising:

(a) a compressed air source in communication with said combustion chamber, said compressed air source including a compressor and a compressed air conduit communicating between said compressor and said combustion chamber and said compressed air conduit further comprises (i) a reservoir for accumulating and storing said compressed air, (ii) a heat rejecting portion for cooling said compressed air, (iii) an outlet portion for conveying pressurized air to said combustion cylinder, (iv) a hot conduit for conveying uncooled compressed air to said outlet portion and (v) a cool conduit for conveying cooled pressurized air from the heat rejection portion to said outlet portion and at least one valve communicating between one of said hot conduit and said cool conduit for adjusting the proportion of cooled compressed air and uncooled compressed air for adjusting the temperature of the pressurized air in said outlet portion.

Claim 24. (Currently Amended)-The combination of claim 23 wherein

said at least one combustion chamber includes a piston mechanically coupled to a crankshaft and said compressed air source includes a compressor powered by a compressor shaft and wherein said crankshaft and said compressor shaft are mechanically coupled such that the speed of rotation of said compressor shaft ~~may be adjusted~~ is adjustable in relation to the speed of rotation of said crankshaft so that effective compression ratio of said engine may be adjusted.

Claim 25. (previously amended) In combination with an internal combustion engine of the type including a combustion chamber which oscillates between a minimum volume and a maximum volume during alternating expansion portions and contraction portions of successive cycles for causing powered rotation of a crank shaft, a system for injecting compressed air into said combustion chamber comprising:

(a) a compressed air source in communication with said combustion chamber including a compressor powered by a compressor shaft, said crankshaft and said compressor shaft mechanically coupled such that the speed of rotation of said compressor shaft may be adjusted in relation to the speed of rotation of said crankshaft so that effective compression ratio of said engine may be adjusted.
